Zip Drive on a C-64

NOTE - This piece used to exist at http://www.geocities.com/cdsixfour/zipdrive.htm

Author unknown

There's the zip drive attached to my system

Yes, that's right. It IS possible to attach a SCSI zip drive to a Commodore 64 system and be able to use it. This is provided you have a CMD HD. In fact, it's probably also possible to attach MO disk drives and other SCSI disk drives using the same method - although I haven't tried anything else but a zip drive. For me, a 100MB zip drive is sufficient enough. Not only that, but the 250MB zip disks are harder to come by where I live.

There are two methods for connecting extra SCSI drives to the HD. My method, and HD-ZIP.

The method I will be describing is my own tried and tested method. It requires no drivers or external software to operate, and will share your CMD HD partition table. HD-ZIP, is another method contained in a program set that has specific programs that need to be run from floppy in order to operate. This other method is able to give each zip disk it's own partition table. You can find the program set here under the name of HD-ZIP (By the way, there is lots of other useful stuff on this site too!). HD-ZIP also contains a copy of HD POWER TOOLS - which is a necessary program to set up your HD system to use an external SCSI drive for my method.

Question: Why would anyone want to do this? What are the benefits?

Good question. What would you do with an extra 100MB to 250MB in addition to a Hard Drive that has plenty of space already? Well, supposing your HD is full (maybe one of those old 40MB models), adding another drive to it will expand its capacity. A zip drive is one way to do this, and you will be able to expand your system exponentially (virtually unlimited by the number of partitions you can have - one of the drawbacks of having a CMD HD) depending on how many zip disks you have. The other good reason to have a zip drive is to back-up your CMD HD on a portable (and cheaper) media in case the HD suffers some really bad corruption or physical damage in the future - or should you want to replace the mechanism. The third good reason is that, if done properly, you can even swap zip disks between different users. You can access your zip drive *almost* as if it were a separate drive. And the best part is that 16MB CMD Native mode partitions are now PORTABLE!

Question: Are there any drawbacks?

Unfortunately yes. This basically depends on which method you use to access your zip drive with. However, it is possible to operate both methods at the same time! Below is a little chart to show the drawbacks of each method. Note that both methods cannot give the zip drive it's own serial device number:

**My method drawbacks:** To install an external zip drive on your system, your HD will have to be full with partitions in the first place. If you alter the contents of the partition structure in the Hard Drive after you have the zip drive working, you risk altering the zip drive's partition structure (and "corrupting" disk data in there! So remove the zip drive from the system before you do this!) and effectively making the zip drive unworkable until you fix the problem. Also, since the zip drive uses the same device number as the HD, other programs that won't allow you to flip partitions mid-program, or give you a drive channel will give you some problems. Finally, the last problem is if the partition structure of a zip disk doesn't match the partition structure you have allocated for your zip drive, you won't be able to read the disk. This problem is easily fixed however by making the partitions under zip control match those of the zip disk. However, to do this should you need to, you will need to hang on to a blank diagnostic zip disk for this purpose.

**HD-ZIP drawbacks:** You need to create a new system on each disk that you use. You will also need to continue to load a small program to flip from the HD to the zip disk drive space. This has to be done quite a lot during disk set-up because any reset to the HD will set you back into the HD partition table. This swap program will probably have to stay on one other device permanently - because at times you need to leave the HD in configuration mode and will be unable to use the HD or zip drive to load diagnostic programs. Apart from these issues, the biggest problem with HD-ZIP is the inability to use both drives at the same time under another program - this unfortunately includes copiers! It therefore means that you cannot copy from the HD to the zip drive unless you route the data through another device - flip to the zip drive, and copy it back. This should be no problem if you happen to have a RAMLink with 16MB in it - but not all of us do. This is unlike my method where you effectively copy from a HD controlled partition to a zip drive controlled partition.

A personal note: Since I have used both methods, I have come to appreciate my own method as opposed to HD-ZIP. To me, the inability to copy from the HD directly to the zip drive was enough for me to discard the HD-ZIP method. I wished to use the zip drive to backup my Hard Drive and HD-ZIP doesn't cater for that. I don't mind that each zip disk I use doesn't have it's own partition table. With 100MB to play with, all I needed was a few 16MB Native mode partitions that weren't pressing my HD partition system too much.

After all this talk, someone out there will question the use of an INTERNAL Zip drive as opposed to an EXTERNAL one we are using. There is a difference if you use an INTERNAL zip drive as opposed to the external type. An INTERNAL zip drive has to be set to SCSI device 0, and can have a system created on each disk complete with DOS and partition structure. I don't have a system like this, and this is only what I have heard about INTERNAL zip disks. Since I have only achieved attaching an external drive to a CMD HD, that is what I will be discussing. Personally, I think an external drive is better to have anyway. I wouldn't want to get a CMD HD just so I can rip out the HD mechanism already in there.

The following instructions show you how to connect a zip drive using my own method. HD-ZIP has it's own set of instructions within the self-extracting archive it comes in. So if you are still interested in the HD-ZIP method - read no further.

**INSTRUCTIONS FOR ADDING A ZIP-DRIVE (my method)**

Ok then, what will we need?

A SCSI zip drive - as far as I know, there are 100MB models and 250MB models. Personally I have the cheaper 100MB model, but the 250MB model should work just as well. You can even use zip drives made by other manufacturers other than Iomega. Just as long as they are SCSI (and NOT the Parallel model) - no problem.

**Zip disks** - A bit obvious this one. You'll need them to save data onto. It doesn't matter whether you get Windows or Mac formatted ones cause we're going to be wiping their formatting over with CMD's HD DOS anyway. If you want to, you can use LLFORMAT to clean format your zip disks and check them for bad blocks after you have added the zip drive to the system and before you start using them. However, it is important to note that it would be wise to keep at least one intentionally BLANK zip disk lying around in your collection AT ALL TIMES. Should you ever need to adjust the partition structure allocated to your zip drive, or reinstall the zip drive in the HD system at a later date, a blank zip disk is necessary to facilitate this.

An RS-232 cable - These are basically male-male cables that use the D25 pin structure on both sides of the cable. It's needed (obviously enough) to connect to the female SCSI plug on the CMD HD and the female plug on the back of the zip drive.

**CMD Hard Drive** - You will need one of these to run a zip drive. The reason is that the HD contains the SCSI controller, DOS, and support electronics that are necessary to run the zip drive from a C64. Unlike the PC, we don't need to install any drivers in our C64 or Hard Drive! ;)

CMD Utilities - There is one program on this collection that is indispensable if you are intending to use a zip drive on your system (and have it work nicely). That program is the HD POWER TOOLS program. You will need it to edit a 1541 partition to extend it completely to cover every single last block on the Hard Drive. More on this later. Also, the FOREIGN CREATOR program is recommended if you want to fill your Hard Drive up temporarily to use the zip drive. If I remember correctly, the HD POWER TOOLS program should be available off the CMD Homepage in the "Files" section under "HD". However, in the case of the "Files" section being down, you can still purchase a copy of "CMD Utilities" directly from CMD. I strongly recommend getting this collection for some of the other utilities as well as the ones I'm talking about.

HD Utilities - Obviously you should have these when you got your CMD HD. The programs we will concern ourselves with are the HD-TOOLS, and ADD DRIVE programs. You may also like to use LLFORMAT to clean format any zip disks you buy with Windows or Mac formatting on them. The program will let you select the zip drive after you've added it, and once the format is finished, it will check the zip disk for bad blocks as well.

So let's get started:

First, plug in your zip drive to the power and to the SCSI port on the back of the HD. While it is on, you can put your intentionally blank zip disk in there. I mentioned before the need to have one of these at hand at all times.

As stated before, the zip drive will not work unless the HD is full to the point where it cannot create more partitions. If your HD is not already full, then fill it. If you only want to make a back up of the HD's contents, then use the FOREIGN CREATOR to fill all the space in the HD with a foreign partition. You should ideally fill close to all the space, but leave 683 blocks at least and then create a final 1541 dummy partition that we will edit to fill the HD's space ENTIRELY in a moment. Once you have done this, you should attempt to create another partition on the system. The HD-TOOLS program will display that due to insufficient space, you can't. The program will also display the remaining blocks that couldn't be filled. WRITE THIS NUMBER DOWN AND MULTIPLY IT BY 256. The resulting number will be needed when we get to the HD POWER TOOLS program. The number is the number of bytes we will need to increase our 1541 dummy partition by to completely fill the Hard Drive so there are zero blocks left in it.

Next, we will open up the HD POWER TOOLS program and make a backup of your partition table. The reason for this is so if there are any problems, you can resurrect your HD partition table.

Just a few things to note here:

I WILL NOT BE HELD RESPONSIBLE FOR ANY DAMAGE OR CORRUPTION YOU DO TO YOUR HARD DRIVE WITH THIS PROGRAM, AND NEITHER WILL CMD.

You read the warning notices, so take caution.

Just remember this one very important point and you will not do any damage.

THE DUMMY 1541 PARTITION YOU WILL EDIT MUST BE THE LAST PARTITION THAT YOU CREATED ON THE HARD DRIVE, AND THEREFORE RESIDES AT THE HIGHEST POINT ON THE PARTITION TABLE.

Now that we have those warnings out the way, do the following. Go to the dummy 1541 partition you created. You will notice that it's size is 175104 bytes. Now, we need to change the size of the partition to completely fill every single last block on the HD. Remember the number you wrote down earlier? It was the number of bytes that we needed to fill the HD to capacity with. Simply change the partitions capacity to the sum of 175104 and the number of bytes we need to fill. Then exit the program. You can check to see that the HD is completely full by attempting to create another partition, and then being told that there are 0 blocks on the drive. THIS IS IMPORTANT. As for the dummy partition we created, it will act just like a 1541 partition. Those extra blocks we put on it cannot be used anyway. It will work as a normal 1541 partition should.

Just in case you are still confused, let me give you an example:

Let's say we filled the HD as much as possible and when we tried to make another partition in HD-TOOLS, we are greeted with a message saying something like "insufficient space - 116 blocks free"

First we get 116 and multiply that by 256. That equals 29696.

When we get to HD POWER TOOLS, we notice the 1541's size is 175104 bytes. Now we add 175104 and 29696 together. That equals 204800. We then change the size of the 1541 partition to 204800 bytes. Et voila... excuse my French.... the HD is full to zero blocks free. Check it out.

Step two. Reset your C64 and load up the ADD DRIVE program. Check out your zip drive and switch it's SCSI device number to whatever you think is appropriate (5 is fine with me - well it's either 5 or 6). Also on my zip drive, there is a switch on the back which would normally on a PC, make it invisible to the system (The "termination" switch). We want to make sure that this switch is off so that the drive IS recognized by the system, or ADD DRIVE won't be able to recognize the drive. The zip drive comes out of the box with the switch in the ON position, so flick this switch OFF.
Next, get the ADD DRIVE program to scan the SCSI port for drives. It should then recognize the zip drive as either a 100MB model or a 250MB model. We then ask the program to add our zip drive to the system. Then we reset our C64 and Hard drive. What the ADD DRIVE program does is add 100 or 250MB worth of blocks to our HD system. When we boot up HD-TOOLS the next time, we can continue to make partitions, except that the partitions will now appear on the zip drive and not the Hard Drive.

Previous documented methods of adding an external SCSI drive required the use of a "bridge partition" to cover the excess blocks that could not be used on the HD, but created a problem by extending into the external drive - thus making the disks incompatible should we try the disk on another system (or new Hard Drive) with a different size/dimensions of the bridge partition cutting into the zip drive space. This problem is now a thing of the past, now that we can set our Hard Drives to 0 blocks at any time. Yay for us!

At this point, you may want to use LLFORMAT to cleanly low-level format the zip disks you have before using them. This step is completely optional. The bonus with doing this however is that you remove the old Windows or Mac formatting completely off the zip disk and, check the zip disk for any bad blocks before you start using it. LLFORMAT will allow you to select which SCSI device to format. Just make sure that you format the zip drive and NOT your Hard Drive by accident!

The last step is to create more partitions on the system with HD-TOOLS. From here on in, the partitions you create will be entirely on the zip disk. Since this space is being allocated under the system, ALL zip disks you use on your zip drive will have the SAME partition structure. Therefore, choose carefully which partition types and sizes you select for ALL your zip disks. For me, I chose 6 Native mode partitions consisting of the maximum 16MB each, and 2 1541 partitions. That all managed to fit on a single 100MB zip disk. When I want to store a 1541 disk on a zip disk, I will probably zip-pack it onto one of the zip disk's native partitions or maybe one of the 1541 partition I created.

An essential point to remember here is that when you create the partitions for the zip drive, A BLANK ZIPDISK MUST BE IN THE DRIVE. HD-TOOLS will format the zip disk in the drive after you create the partitions. DON'T leave a disk with data you want to keep in the zip drive at this point - it will be LOST. For this reason, always have a blank zip disk at hand (I'm beginning to repeat myself a lot here) should you need to reinstall the zip drive or change the partition structure of the zip drive. ALWAYS keep a blank disk in your collection of zip disks.

After the partitions have been selected and installed in the system, other zip disks must be formatted first before they can be used. This is done simply by sending the @N (new) command to the partitions under the zip drive.

So that's all the details of adding the drive.

To use the drive, you simply save your data into the partitions under zip drive control. You can just as easily load things from there in exactly the same way you would with the HD. If you have native mode partitions, you can even make subdirectories and the like. One thing that has to be taken into consideration however, is that whenever you change zip disks, the HD will have to be reset manually as well by pressing the RESET button on the CMD HD. THIS IS IMPORTANT! The reason is so the HD doesn't get lost. Supposing you were in two subdirectories deep in a native partition on zip disk #1, and then you swap to zip disk #2 only to find that the HD thought you were in a subdirectory in zip disk #1 when the current disk doesn't even have any subdirectories made in it! Embarrassing, no?

In order to back up your HD, you will first need to follow all of these steps until your HD and zip drive partitions are all configured. Then use MCOPY to copy partitions over to the zip drive (who needs BCOPY?). Be patient as it can take a while to copy 16MB from a native mode partition to the zip drive. You could, of course, file copy things but you'd be there forever......

Some things to remember:

- DON'T change the Hard Drive's partition structure (if you can avoid it). If you do change it, make sure you remove the zip drive partitions and then use ADD DRIVE and REMOVE the Zip drive from the system first. If you leave the zip drive and it's partitions on the system, the zip disk in the drive will have it's data pulled down into an unreadable format as HD-TOOLS tries to rearrange the system. If you ever have to adjust the Hard Drive partition structure, you will have to fill the Hard drive again COMPLETELY as before, add the zip drive again, and recreate partitions for the zip drive to use that are compatible with your disks - in that order.

- DON'T forget to fill the HD completely so there are NO BLOCKS LEFT on it. DON'T try the "bridge partition" method as was once suggested by CMD. Whilst it is possible to save and load things on a zip disk without filling the Hard Drive completely and leaving some space (Thus dodging the need to use HD POWER TOOLS), it is very messy. If you fill the drive and then create a bridge partition to fill the gap, and then create partitions, there will be no chance of you being able to read from the zip disk again unless you have the same size drive, the same partition structure, and exactly the same block gap between the drives. This is not useful at all if you are going to back up your system onto zip disks should your CMD HD (god forbid) blow up. Neither will it allow you to swap zip disks with other users. Lastly, the bridge partition is useless because it straddles two devices - unlike our extended 1541 partition.

- DO take note of what kind and size of partitions you have placed on your zip disks. Without this, other people cannot fix their systems to read them, and more importantly, you won't know how to read them in case you need to recreate your Hard Drive. I suggest writing this info on your zip disks' labels.

- REMEMBER, you will need a blank zip disk in order to create partitions on the HD system that the zip drive can use. HD-TOOLS will format the zip disk on the creation of these partitions, so ensure there is a disk in the zip drive, and it is BLANK. Essential to have one
of these around if you ever need to reattach the zip drive.

To Summarize:

(1) Fill your HD and leave JUST ENOUGH space for a final 1541 partition. Also ensure you have enough partition slots left in the HD system to use for the zip drive.

(2) Create the 1541 dummy partition. Then try and make another partition. Take note of the number of blocks left in the system that cannot be made into a partition. Multiply the number by 256. Write this new number down.

(3) Use the HD POWER TOOLS program to extend the 1541 partition to fill every single block in the HD. Add 175104 and the number you wrote down earlier together. The sum of these numbers is the new length you enter into the size field of the 1541 partition to created before.

(4) Ensure the "Termination" switch on the zip drive is set to OFF. Insert your blank zip disk. Add the zip drive to the HD system with the ADD DRIVE program.

(5) Create more partitions on the system with HD-TOOLS that you want to use for your zip drive.

(6) Enjoy using your zip drive for whatever you want!

Return to the CUE HD-Zip Page
Formatting 100 MB Disks for a CMD/ZIP Drive

One of the best ways to increase the usefulness of your CMD Hard Drive is to install an internal SCSI ZIP Drive by Iomega. The advantage is that if your hard drive ever "konks out" on you, you will not lose all your data. Just replace your drive and you can continue using the same disks! If you have a large hard drive of one gigabyte or more and it bites the dust, you could lose everything. Thus, Iomega 100 MB Zip disks provide a very versatile answer to the hard drive needs of today’s Commodore user.

Cost may be a factor, however. Hard drive mechanisms are getting cheaper and cheaper, but Iomega disks are not. Two years ago, when I first converted my CMD/ZIP drive, the cheapest disks I could find were about $10 apiece. The price is the same today. So ZIP drive memory costs at least $100 per gigabyte. That may seem high to some of you.

Should you decide to convert your CMD HD to a ZIP drive, you may want to know how challenging it will be to format them. First, all Zip disks come formatted (IBM-style). CMD has a "low format" option (called LL FORMAT) which may come in handy someday, but you will not need it to format Zip disks.

Instead, you will need to run a program called "CREATE SYS.64 (or 128)." This puts the information on the disk that will allow you to alter the format from IBM to Commodore mode. Unfortunately, this can be pretty damn tricky. (Disclaimer: My information is based purely on my own personal experience.)

At first, I tried to run this program from a partition on a second hard drive. It would not work. Finally I found the note at the bottom of page A-10 in the HD Manual which says, "CREATE SYS should only be loaded and run from a floppy disk drive. Other programs stored on the floppy disk will be needed while the program is running, so do not remove the disk during this process."

Therefore, I suggest that you keep your original "CMD HD UTILITIES" disk in a safe place, and that you run the "CREATE SYS" program from that disk.

Still, problems continued. I called CMD and discovered that the parallel cable must be unplugged before this program can be run. So I unplugged the parallel cable and STILL couldn't get a READY prompt!

The above program would not work as long as BOTH my 40MB HD and my CMD/ZIP HD were turned on. In order to run the "CREATE SYS" program, the extra hard drive had to be turned off. I STILL had a hard time getting the READY prompt on the screen as long as the "unaltered" Zip disk was in the drive. (God only knows how I got the first one formatted!) So I put in a good Zip disk, the READY prompt appeared on the screen, and then proceeded to run CREATE SYS on my "vital-data" storage disk instead of the one which needed to be formatted. To add further humiliation, this is a stupid mistake which I have made, not once, but TWICE!!

So my advice to you is this! In order to get the READY prompt with an unformatted disk in the CMD/ZIP drive, press the 'SWAP 8' and 'SWAP 9' buttons together and hold them down while pressing the RESET button just once. When the lights stop flashing, release the SWAP buttons. You should immediately see a READY prompt on your screen. This option is much better than placing a good formatted disk in the drive and running the risk that you will forget to switch it out before actually running CREATE SYS.

What can you do if you corrupt a valuable storage disk in this manner? All is not lost! The CREATE SYS program initializes your HD DOS system tables. In other words, if you mistakenly run this program on a valuable storage disk, all you actually corrupt is the partition table! The HD Manual states (p. A-10), "You may also use this program if you want to remove ALL partitions from the drive quickly." The good news is that your data is still safe, the bad news is that you will need to restore your original partition table.

Replacing the partition table was easy for me because I only use one, and I use it religiously. My first partition is always a 1581 partition. Then I follow that with six 16 MB native mode partitions. That way I only have to put 7 partitions on each disk with the convenience of having my 1581 partition up front.
I truly recommend that you too settle on one simple partition plan and use it repeatedly. The high advantage is that you can switch Zip disks in and out at will without having to go back and "retool." Otherwise, you would have to open the "TOOLBOX" in WHEELS and reinitialize the CMD/ZIP drive everytime you changed disks. That can be aggravating. By using the same partition plan on all my Zip disks, I avoid such delays. Another advantage is that I can "save" the partition layout, gleaned from a good working disk, and then use that file to restore the partition table on any that have been corrupted.

For this you will need the "CMD Utilities" disk which contains advanced programs. One such program is HD POWER TOOLS. This program has a big warning at the beginning, but you will not need to worry about a thing if you follow these directions. When you choose to continue, the screen will give you four choices.

1. EDIT PARTITION TABLE
2. BACKUP PARTITION TABLE
3. RESTORE PARTITION TABLE
4. QUIT

(Select 1-8)

In this case, I put in an already formatted disk and select #2. It tells me that the partition file must be saved to a floppy disk. I must type in the number of the drive containing that disk. Well, the "CMD Utilities" disk is in the 1571 drive, so I select the 1581 to store the partition file upon. Then I am asked to type in the name of that file. I type: ZIP1.PARTITIONS.

The HD POWER TOOLS program runs thru all 254 partition possibilities. Why it insists on searching for partitions which don’t exist is beyond me, but it continues until 254 possible partitions have been counted off. When finished, it creates a file that can now be used to restore the partition table to the data disk which I accidentally corrupted with CREATE SYS, as explained above.

Now I put that disk into the CMD/ZIP drive and select the option #3. Again the program counts thru 254 possible partitions. When it finishes, my "damaged" disk is fully functional again! The lesson here is to save the file(s) of your partition table(s). Then if any partition table is damaged, you have a chance to restore it without losing your valuable data!

Let's get back to the disk that we wanted to change from IBM to CBM format. Place it in the CMD/ZIP drive and the "CMD HD UTILITIES" disk in the 1541/1571 drive. Run the CREATE SYS program. When it is finished, you will want to divide it into partitions. You have two choices. You can either use the HD-TOOLS 64 (or 128) program to partition it, or you can select and install a previous partition table as I explained above. In my case, it is a lot faster to put the "CMD Utilities" disk in the drive and run the HD POWER TOOLS program again. I select option #3 and type in ZIP1.PARTITIONS. The complete partition table is installed with no muss or fuss! (You will need to format each partition as you use it, but I maintain that this is a lot faster than using HD-TOOLS to create partitions one at a time.)

When you are finished, you will have to use HD-TOOLS again to adjust the drive number. Running either CREATE SYS or HD POWER TOOLS will automatically change the HD's drive number to 12. You will probably want to reset it to a drive number between 8 and 11.

If you have any questions about using ZIP drives with the Commodore which I might be able to answer, you can write to me at:

Sincerely,

K. Dale Sidebottom
June 28, 2011

To Jim Peters,

The "File Copy" called "Formatting 100 MB Disks for a CMD/Zip- Drive" explains how I formatted these many years ago. In trying to duplicate this feat recently, I discovered that the info may be slightly wanting. For instance, I was forced to run LLFORMAT with the Turbo speed switched off before I could run CREATE SYS.128. After running both of these programs, I just run HD POWER TOOLS, select the 3) RESTORE option. Select the drive in which the HD POWER TOOLS is located and then the name of the partition file, currently called ZIP1.

Please check out the GEODOS program if you haven’t already. It is irreplaceable in the things it can do. But sadly, it will be corrupted over time, so try to keep an uncorrupted copy handy and just replace the seven files whenever you see it freeze and hear “ping”!

Best of luck in your enjoyment of these Commodore products.

Dale Sidebottom
